Projections of Economic Activity for Air Quality Control Regions

Bureau of Economic Analysis, Washington, D C

Aug 73

ABSTRACT

Projections of economic activity are presented for 242 Air Quality Control Regions. Data are given for thirty categories of earnings by workers which include, for example, manufacturing, mining, agriculture, wholesale and retail trade and services. Both historical data from 1962 through 1970 as well as projections to the year 2000 are shown.

5. PRESENTATION OF DATA

1. INTRODUCTION

This report presents projections of economic activity and population for 242 of the Nation's Federal air quality control regions (AQCR's). 1/

These AQCR projections are an extension of the OBERS 2/ water resources program which has produced historical and projected measures of economic activity for the Nation and its subareas. The measures produced include personal income, population, per capita income, employment, and earnings, with the last item shown for each of 28 industries. Historical data are presented for 1962, 1968, 1969, 1970, and projected data for 1975, 1980, 1985, 1990, 1995, and 2000.

1/ These AQCR's are officially designated in Title 40, Part 81, of the Code of Federal Regulations. The geographic definitions and accompanying maps of the 247 AQCR's (including those located in American Samoa, Guam, Puerto Rico, and the U.S. Virgin Islands which are not presented in this report) can be found in Federal Air Quality Control Regions, published by the Office of Air Programs, Environmental Protection Agency (EPA) in January 1972.

The classification used in this report agrees with the cited geographic definitions with the following exceptions. The Standard Metropolitan Statistical Areas (SMSA's) of Boston, Massachusetts; Binghamton, New York; Wilmington, Delaware; Parkersburg, West Virginia and Youngstown-Warren, Ohio which are subdivided by EPA into two or more AQCR's have been assigned to the AQCR which contains the major city because of data limitations and commutation problems.

2/ The OBERS program, initiated at the request of the Water Resources Council (WRC) is a joint undertaking of the Bureau of Economic Analysis (BEA) of the Department of Commerce and the Economic Research Service (ERS) of the Department of Agriculture. This program acquired the acronym of OBERS in the mid 1960's at which time BEA was named the Office of Business Economics (OBE) and is a combination of OBE-ERS. The widespread acceptance of the term has led to its continued use as a descriptive title of the projection program even though OBE has been renamed BEA.

These projections, as with all efforts to look into the economic future, are based upon an extension of past relationships. The methodology used has four characteristics which distinguish the results from those which would result from a simple linear extension of trends at summary levels.

First, the basic projections were made for 173 economic areas which cover the Nation. These areas were delineated by BEA on the basis of criteria that make them especially suitable for economic analysis and projection.

Second, the economic area projections were made within the framework of projections of the overall U.S. economy. That is projections of population, employment, income, and earnings were made first for the Nation as a whole and then disaggregated geographically.

Third, the projections were based on the assumption that people migrate to areas of economic opportunity and away from declining areas. Accordingly, projections of area income and employment were prepared first, and projections of area population derived from them.

Fourth, projections of income and employment were prepared for as many as 37 individual industries in each of the 173 areas. Various methods were used to make the projections, depending upon the individual industry's role in each area's economy. However, the methods used insure that in each of the 173 areas the projected income and employment constitute an economy with an internally balanced structure. Because the projections were prepared in industrial detail they reflect the effects of variations in growth rates among individual industries, which makes it possible for the projected overall economic path of an area to depart substantially from its past trend.

The AQCR projections in this report were prepared by disaggregating the economic area projections prepared under the OBERS program into the geographic detail necessary to reaggregate them into AQCR's.

The methodology used in breaking out the AQCR projections consisted of the following steps. First, for each projected item and for each past year, the AQCR segment of each economic area was expressed as a percent of that item's value for the entire economic area of which it is a part. This trend in share was then extended on the basis of a fitted least squares regression line. Projected percentages were applied to the parent area totals to obtain absolute values, with the results subjected to judgmental review and adjustment by regional economists. This procedure builds on the large amount of analytical work done for the Nation and its economic areas and yields a set of projections which are consistent with those being used by other agencies in planning. The projections at the economic area level have been reviewed by many State and Federal agencies. Their suggested changes have been evaluated and taken into account. The AQCR breakouts reflect these reviews. 3/

2. NATURE OF THE PROJECTIONS

These projections, as are all other projections, are conditional forecasts of the future. Inasmuch as it is not possible to foresee the future, however, projections must be based on an extension of past relationships believed to have future relevance for the measures being projected. The choice of the past relationships to be extended and the methodology for extending them are based on assumptions, some of which are stated explicitly and some of which are implicit

---

3/ A more complete description of the procedures employed in making these AQCR projections is included in a later section of this report. A detailed explanation of the concepts and methodology used in preparing the OBERS projections is contained in a report published by the WRC entitled, The 1972 OBERS Projections - Regional Economic Activity in the United States by BEA Economic Area, Water Resources Region and Subarea, and States, Historical and Projected 1929-2020, July 1972.

in the projection methodology. The projections represent estimates of economic activity expected to develop during the projection period if all assumed conditions materialize. The assumptions chosen represent those conditions believed to have the greatest probability of realization. Thus the projections represent an attempt, imperfect though it may be, to forecast the economic future with the specification of assumptions and methodology introducing maximum objectivity into the process and giving the user a basis for appraising the validity of the projections. The specification of assumptions and methodology facilitates the construction of alternative projections based on different assumptions and provides a foundation for the evaluation of program-oriented "what if" questions. In particular alternative projections are useful to reflect assumptions that are likely to materialize if a special program or policy is undertaken to bring them about.

2.1 Reliability

Differing orders of reliability characterize the various elements of the projections. These differences are caused by variations in the length of the projection period, the size of the aggregate being projected, potentials for product substitution, and many other factors. A general understanding on the part of the user of the degree of reliability associated with any projection should help avoid misinterpretation and inappropriate use. However, levels of reliability for the projections cannot be stated in statistical terms. They can only be evaluated qualitatively by the user with the results interpreted in light of the uses to which the projections will be put.

Long range projections are less reliable than are those made for short periods; projections of small aggregates are less reliable than those of large magnitude. Thus, projections for 1980 are more reliable than those for 2000, and the reliability associated with the projections for any given industry in an AQCR is less than that for the same industry

in the Nation as a whole. The reliability of the projections for a minor industry will be much less then that for the more aggregated estimates of total production, total employment or total income.

Another major factor in reliability of the projections arises from differences in the confidence that can be attached to the basic assumptions used. Some assumptions are highly reliable characterizations of the future while others are more conjectural. A projection of the labor force at the national level for 1990, for example, will almost certainly be quite accurate because the labor force for those years will be drawn almost entirely from a population whose number and age distribution are known quite accurately at the present time. The only major uncertainty is the proportion of the population that will desire to enter the labor force and this fraction exhibits substantial stability. However, projection of the labor force or of employment in a given subnational area is related not only to the current population of that area but also to interregional migration resulting mainly from change in employment opportunities. Such opportunities are among the more difficult elements to project. Therefore, the future labor force of the smaller area, depending as it does on factors which are less certain than those determining the size of the national labor force, is subject to a larger margin of error.

Potential errors in the planning process growing out of errors in the projections cannot be eliminated, but their effects can be minimized through the use of sensitivity analysis and the maintenance of flexibility in plans in order to accomodate deviations from the projections when they occur.

2.2 Assumptions

The projections are based on longrun or secular trends and ignore the cyclical fluctuations which characterize the shortrun path of the economy. The general assumptions that underlie the projections are as follows:

(1) Growth of populations will be conditioned by a decline of fertility rates from those of the 1962-1965 period.

(2) Nationally, reasonably full employment, represented by a 4-percent unemployment rate, will prevail at the points for which projections are made; as in the past, unemployment will be disproportionately distributed regionally, but the disproportion will diminish.

(3) No foreign conflicts are assumed to occur at the projection dates.

(4) Continued technological progress and capital accumulation will support a growth in private output per manhour of 3 percent annually.

(5) The new products that will appear will be accomodated within the existing industrial classification system, and, therefore, no new industrial classifications are provided.

(6) Growth in output can be achieved without ecological disaster or serious deterioration, although diversion of resources for pollution control will cause changes in the industrial mix of output.

The regional projections are based on the following additional assumptions:

(1) Most factors that have influenced historical shifts in "export" industry location will continue into the future with varying degrees of intensity.

(2) Trends toward economic area self-sufficiency in local-service industries will continue.

(3) Workers will migrate to areas of economic opportunities and away from slow-growth or declining areas.

(4) Regional earnings per worker and income per capita will continue to converge toward the national average.

(5) Regional employment/population ratios will tend to move toward the national ratio.

3. BASELINE PROJECTIONS

The estimates of future economic activity in this report are labeled baseline projections with the term "baseline" denoting a frame of reference for use in the planning or evaluation of an action or operation. These baseline projections are a best estimate of what can be expected to materialize if there are no policy or program changes of an unusual and unforeseen nature or magnitude in the factors which determined past trends. Of course, certain of the factors have been changing over time and will continue to do so in the future. This continuation of change is embodied in the projections.

The projections are in no sense a goal, an assigned share, or a constraint on a region's economic activity. Moreover, they carry no connotation as to desirability or undesirability. Especially, they should not constrain the planner from considering alternative levels of growth higher or lower than those in the baseline, which can be achieved through program planning.

3.1 Use of the baseline projections

The baseline projections serve at least three uses. First, a primary use is in the estimation of future amounts of pollutant emissions. This estimation will usually entail the application of emission coefficients to the projected level of economic activity. In this use, the planner may wish to vary the projection in order to test the sensitivity of plans to different levels of economic activity, and to introduce flexibility in the plan in order to accomodate the uncertainty of future conditions.

Second, analysis of the baseline projections may reveal unsuspected future economic problems in an area. These can then be averted or ameliorated through corrective action.

Third, the baseline projections provide a benchmark framework for evaluation purposes. If a remedial or developmental program is proposed for an area, the projected baseline economic activity in the area

can be modified to reflect the anticipated effects of that program. Comparison of the new projections with the baseline projections will provide a quantitative measure of the gross effects of the program in each region affected. Since there may be positive effects in the area of developmentand negative effects in the same or other areas, the net effect of the program is obtained when all regional gross effects are summed. Use of baseline projections as a foundation for the impact evaluation process in air quality planning rests on a two-fold premise. First, the baseline projections used in the planning process represent a dynamic economy at full employment and approaching equilibrium conditions. Second, changes in income flows are generated by investments which are triggered by changes in the use of economic resources. Assuming initial approximate equilibrium conditions, these changes must arise from a shift in demand and/or supply functions for goods and services affected by a given project investment or program.

Although projections are an indispensable planning tool, experience with the preliminary OBERS set issued in 1968 has revealed certain misinterpretations which detract from effective planning. For example, application of the widespread, but erroneous, notion that the OBERS projections are economic quotas to be met by specified regions or subareas eliminates the consideration of alternative regional development programs which might result in more nearly optimal solutions to resource development and management problems. Also, the idea that the resources of one area can be developed and managed satisfactorily without consideration of the impact of such actions on the economy of other areas may lead to erroneous conclusions concerning the economic justification of the actions under consideration. BEA is developing a system to quantitatively measure the economic impact of public investments and programs on regional economies.

4. PROJECTION METHODOLOGY

The AQCR projections were made in five major steps.

First, population, employment, GNP, personal income and earnings were projected for the Nation. Second, the projected national totals of output, employment, and earnings were disaggregated industrially on the basis of projected trends in industry shares of the national totals, modified as necessary by projected trends in the interrelationships of the three aggregates for each industry.

The third step was to allocate the projected national totals of income and employment to the 173 economic areas into which BEA has divided the country. This was done by extending past trends in income and employment on an industry by industry basis.

The fourth step was to derive area population totals from projected area employment.

The fifth step was to disaggregate the projected economic area figures so as to obtain the AQCR projections.

The projection procedure was not a mechanical one. At various points in the process, it was essential that judgment be brought to bear, both in estimating the future rate of change in the industrial composition and location of production and in checking the consistency of the projections. In particular, where employment and earnings were projected separately, it was necessary to review the implied industrial and regional patterns of earnings per worker in order to insure reasonable relationships between employment and earnings.

The decision to derive regional projections through the disaggregation of national totals instead of through the independent projection of each component in each region was based on the assumption that the larger the economic area, the more adequate and reliable are the available statistical measures and the more reliable are the projections that can be made. This assumption applies also to the decision to derive

projections of industrial detail at the national level by first projecting national employment, output, and earnings and then disaggregating them into national totals for individual industries. Of course, it should be obvious that the disaggregation approach is also subject to substantial error as is any procedure for forecasting the economic future.

4.1 Gross national product

The initial step in preparing the national projections was the projection of the gross national product. This was done by multiplying projected manhours worked by projected product per manhour. The variables which entered into the determination of manhours worked include the working age population, labor force participation rates, general government employment (civilian and military), and hours worked per year per man.

The Bureau of the Census makes several different national population projections at any given time, with the birthrate assumption being the varying element. In light of all factors that could be ascertained in mid-1969, when the decision was made regarding the projected national population to be used, the "C" series was selected. Of the five Census Bureau population projections, this series has the second fastest growth rate. It assumes a trend toward a total fertility rate of 2,787 births per 1,000 women in the year 2000 which is below the rate of 3,300 in 1962 through 1965, but above the rate of 2,111 per 1,000 which would maintain a constant population, and above the preliminary 1970 rate of 2,472. The "C" series shows national population increasing from 203 million in 1970 to 400 million in 2020, an approximate doubling in 50 years. The "E" series, which utilizes a lower fertility rate than does the "C" series and for that reason would be the choice of many persons today, is 4.4 percent lower than the "C" series in 1990, 12 percent lower in 2000, and 23 percent lower in 2020.

The working age population, labor force participation, unemployment rate, and hours worked per man per year were each projected separately using all information and analyses available in each case. The population of working age by age and sex is a subset of the total population. The labor force was derived by applying age-and sex-specific participation rates developed by the Bureau of Labor Statistics to the working age population. A 4-percent unemployment rate was adopted as representing full employment nationally. Hours worked per man per year in the private economy were projected to decrease by 0.25 percent per year, compared to the post-World War II average decrease of 0.4 percent per year.

Real gross product per manhour (productivity) in the private economy increased at an annual rate of 3.2 percent from 1950 to 1968. The projection puts productivity growth at an annual rate of increase of 3 percent from 1968 to 2020. This projected rate is somewhat lower than the 1950-68 rate to allow for the fact that some part of the productivity growth in 1950-68 was attributable to a massive movement from farm to nonfarm work which cannot be repeated on a similar scale in the future. There is a variety of opinion on the validity of the 3-percent rate. Some forecasts would lower the projected rate still further because of the projected shift in work force distribution away from higher productivity manufacturing to the lower productivity service industries; others would raise it on the grounds of expected technological advances.

Private gross product was projected by multiplying manhours in the private sector by private gross product per manhour. Constant dollar government gross product was projected in accordance with conventional national income and product accounting practices as the projected number of general government employees times average compensation in the base year (1958).

The sum of projected private and government gross product equals projected constant dollar GNP, which is projected to grow at an annual rate of 4 percent from 1968 to 2020.

Since measures of gross regional product have not been constructed, it was necessary to translate GNP into national measures which could be prepared regionally.

4.2 Personal income and earnings

The measures chosen for this purpose were personal income and its earnings-of persons component (the sum of wages and salaries, other labor income, and proprietors' income). The choice rested on three considerations. First, personal income has a comparatively constant relationship to gross national product; second, its regional location is clear and can be measured with current data sources; and, third, the methodology for preparing regional estimates of personal income had already been developed.

Projected national personal income was derived from the historical relationship between constant dollar personal income and constant dollar GNP. A function was fitted mathematically to past values of the income/GNP ratio and extended to 2020. The projected ratio for each decade was applied to projected GNP to derive projected personal income.

In a similar manner, the ratio of earnings of persons to total personal income was projected and applied to projected personal income in constant dollars to yield projected earnings in constant dollars.

4.3 Industry detail

The projected values of three national aggregate measures were disaggregated industrially. The three measures are gross product (which at the industry level is gross product originating, or GPO), earnings of persons, and employment. The disaggregation was into 37 industry groups for which local area data on earnings and employment are available. When the SMSA projections were broken out from the economic area projections the 37 industries were combined into 28. The disaggregation was made by extrapolating 1948 through 1968 trends in the industrial composition of gross product, earnings of persons, and employment. That is, each industry's share in total GNP, total earnings, and total employment

Reproduced from best available copy.

was extrapolated and applied to the projected all-industry totals of GNP, earnings and employment.

The resulting projections of GNP, earnings, and employment for each industry were then reconciled. The reconciliation focused on two major considerations. First, projected industry GPO, earnings, and employment were examined in the light of historical trends in the relationships among earnings per worker, GPO per worker, and earnings as a percent of gross product. Second, those ratio relationships for each industry were reviewed in the light of the corresponding all-industry ratios, t judge how well the projected data adhered to the empirical observation that interindustry differences in earnings per worker and GPO per worker diminish over time.

The national projections of industry employment used the data on "persons engaged in production" that are calculated by BEA as an adjunct to the national income and product accounts. These data are conceptually consistent with the series on gross product originating and earnings. However, the "persons engaged in production" series is not available on a regional basis. The only employment data with adequate industrial detail now available for local areas are from the decennial censuses of population. It was necessary, therefore, to convert the projected national industry employment to the Census employment concepts. This was done by first eliminating government workers from the various industries. The resulting 1960 Census employment figures for each industry were then extrapolated forward by the projected change in the 'persons engaged" series (1970 Census employment data were not available for all States at the time these projections were prepared). Independently projected estimates of government employment were then added to projected private employment in the appropriate private industries to yield national totals of employment for distribution to economic areas.

4.4 Economic areas

Once projections had been made at the national level for gross product, earnings, and employment by industry, the national industry totals were allocated to subnational areas. The areas chosen were the 173 economic areas into which BEA has divided the country as part of its program of regional measurement, analysis, and projection. Each area consists of an urban center and surrounding counties which are tied to the center by economic activity. Each area generally combines place of residence and place of work so that there is a minimum of commuting across area boundaries.

Each economic area has two types of industries. "Export" industries produce goods and services that are for the most part exported to other areas, providing most of the earnings with which the area residents purchase the specialized goods and services of other areas. "Residentiary" industries produce most of the services and some of the goods required by local business as intermediate products and by the household sector. Each economic area approaches self-sufficiency with respect to its residentiary industries.

There is general similarity among economic areas in the interindustry relationships among residentiary industries and between total export and total residentiary industries within each area. Moreover, these interindustry relationships within areas exhibit substantial stability over time, although they do change as a result of secular trends and developmental thresholds (points at which local markets for intermediate or consumer products become large enough for local production to supplant all or a portion of imports). These characteristics of similarity and stability make the BEA economic areas superior for projection purposes to geographic areas delineated in accordance with other criteria. For example, the relationships among industries located within a single county appear to be meaningless and random. Such relationships would acquire meaning, of course, if data were available on the county's imports and exports so that total input requirements of each local industry

could be calculated. However, assembly of such data at the county level would be a near impossibility. Use of the BEA economic areas for projections and analyses makes it unecessary to have such data for residentiary industries, though export-import information is still needed for the export industries.

4.5 Local area economic measures

The local area economic measures used in the projections are population, total personal income, earnings by industry of origin and employment by industry.

Estimates of total personal income, earnings by industry, and the nonearnings component of personal income in each SMSA and non-SMSA county have been prepared by BEA for 1929, 1940, 1950, 1959, 1962, and annually from 1965 forward. These were aggregated to the 173 economic areas. Estimates of employment for 1962, 1965, and 1966 were made by moving census data for 1960 forward with employment data from County Business Patterns, supplemented by data from the American Railroad Association, the American Hospital Association, the Social Security Administration, State employment security agencies, and several economic censuses. Because there is very little commuting across economic area lines, the census-based employment data for economic areas, which reflect residence of the employees, are compatible with the earnings data which reflect place of work.

4.6 Economic area projections: export industries

Projections of employment and earnings in export industries were made industry by industry, for each economic area, on the basis of projections of the trends in the area's share of total national employment and earnings in each industry. The trends in the shares were projected into the future by fitting least squares regression lines to the logarithms of the historical values of the share and to the logarithms of time and

and extending these curves to 2020. The projected shares derived in this manner were modified judgmentally in some cases, mainly where natural resources were expected to be depleted or where the historical data appeared weak or in error. The projected area shares after being forced to total 100 percent, were applied to the appropriate national totals and projected absolute values were calculated.

Earnings and employment in each export industry were projected independently for each economic area. From these, projected earnings per worker were calculated and expressed as a percent of national earnings per worker in the industry. These ratios were used to discover inconsistencies between projected employment and projected earnings. When inconsistencies were found, the data were reviewed in the light of information from other sources and the two projections were reconciled. In most instances, this review pointed clearly to the need for a change in either projected earnings or projected employment, but occasionally compromise was necessary and both were adjusted.

4.7 Economic area projections: residentiary industries

Projected area earnings in each residentiary industry were derived from the following relationships: (1) The projected regional location quotient (LQ) for the industry, i.e., the ratio of the industry's share of total area earnings to the industry's share of total national earnings; (2) the projected national ratio of earnings in the industry to total national earnings; and (3) projected earnings in total export industries in the area.

The area LQ's for each residentiary industry - item (1) above -- were projected as follows: Analysis of changes in the area LQ's of individual residentiary industries from 1950 to 1969 showed that economic areas trend toward self-sufficiency in residentiary industries, i.e., LQ's trend toward 1.0. Analysis also showed that the slope of the trend depends upon the magnitude of the LQ. From this analysis, trend values for change in LQ's were set for several different ranges of LQ value. These trend values were then applied to the LQ of each residentiary industry in 1969 and projected LQ's were determined for 1980, 1990, 2000, 2010 and 2020.

Reproduced from best available copy.

The projected national ratio of earnings in each residentiary industry to total national earnings (relationship 2 above) was calculated from the national industry earnings projections noted as the second step of the overall projections methodology.

Relationship 3 was derived by summing earnings of export industries already projected for each economic area.

Projected earnings for each residentiary industry in each area were derived as follows: First, the projected LQ for each residentiary industry (relationship 1) was multiplied by the projected national ratio of earnings in that residentiary industry to total national earnings (relationship 2). This computation gave the projected share of the residentiary industry in the area's all-industry earnings. These shares were summed for all residentiary industries in the area. Subtracting the sum of residentiary shares from unity gave the export industry share. Division of this share into the projected absolute value of export industry earnings -- already caculated -- yielded projected all-industry earnings for the area. To this total was applied the projected share of each residentiary industry in the area's all-industry earnings (the product of relationships 1 and 2) to obtain the projected absolute value of earnings in eac residentiary industry in each area. The sum of the area values for each residentiary industry was forced to equal the previously projected national total for the industry, thereby keeping the projected series within the framework of the national projections.

A comparable procedure was used to project residentiary employment by area. As in the case of the export industry projections, projected residentiary employment and earnings were reconciled. This took place through the use of the relative earnings per worker.

Certain industries are classed as residentiary in some areas and export in others. For example, in one area, hotels may serve principally the business community and local residents while in another, such as Las Vegas, they may provide recreation for visitors and so form an export industry. Similarly, in one area, printing and publishing may

involve only local newspaper publishing and local business printing, whereas, in another area, it may serve a national market through book and magazine publishing. In each area, employment and earnings in such industries were projected in accordance with each industry's character in that area. This procedure necessitated a break of the projected national totals for these industries into that portion to be treated as export and that as residentiary.

Total earnings, the sum of export and residentiary industry earnings, make up about 30 percent of total personal income. To complete the projections, property income, transfer payments, and contributions to social insurance (which are netted out of personal income) were projected by a modification of the procedure used for residentiary industries.

4.8 Population projections

The natural increase in population in an area - births minus deaths - can be projected quite accurately when the national fertility rate is assumed. The critical element in a local-area population projection made within a given national population total is inter-area migration. As previously noted it was assumed in these projections that the major motivating factor in migration is economic opportunity except in a few areas which attract an especially large number of retired persons. Accordingly, changes in area population were projected as a function of changes in area employment.

Historically, there has been some variation among areas in the ratio of population to employment because of differences in unemployment and in labor force participation. The projection technique recognizes these differences but assumes that they will gradually disappear. As stated in the summary of assumptions, 4 percent unemployment was assumed nationally but not in each individual area.

The projected increases in employment were translated into population changes by applying the projected national population/employment ratio to area changes in employment. In area where retired persons

Reproduced from best available copy.

comprise an especially large proportion of the population -- and measured labor force participation is unusually low -- the retirement population was projected separately from the remainder.

Historically, area per capita incomes have converged slowly toward the national average, and the projected area per capita incomes derived from projected personal income and projected population were analyzed with this in mind. In a few cases, the behavior of projected per capita income suggested need for reexamination and sometimes a modification of the projected components.

4.9 AQCR projections

The final step in deriving the AQCR projections was to separate the projections for the 173 BEA economic areas into AQCR segments. The separation into segments was done by projecting each segment's share of economic area population, personal income, total employment, and earnings by industry, on the basis of historical trends in those shares. Projected AQCR shares were applied to the appropriate economic area totals to obtain absolute values for each AQCR segment. This procedure was applied to both export and residentiary industries, as the disaggregation of area totals into AQCR segments invalidated the functional relationships between export and residentiary industries that hold for economic areas and that can be used at that level to project residentiary industry activity on the basis of export industry activity.

The BEA figures on total and per capita income for AQCR are expressed on a residence basis (income of residents of the area). In some AQCR's, however, income figures on a where-earned basis would differ from those on a residence basis because of commuting across AQCR boundaries. The data used for adjusting the AQCR income series to a residence basis (for the basic data are projected on a where earned basis) are statistically weak and no attempt was made to project such adjustments directly. Instead, per capita income in each AQCR was

projected as a function of national per capita income, and multiplied by projected AQCR population to give projected total personal income by AQCR.

INDUSTRIAL GROUPINGS WITH STANDARD INDUSTRIAL CLASSIFICATION CODES

5. PRESENTATION OF DATA

The following tabulations include a table for the U.S. and for each of 242 AQCR's. Table 1 for each area presents historical and projected measures of population, personal income, total earnings, and earnings by 28 industry groups.

Reproduced from best available copy.

TABLE NOTES

Data may not add to higher level totals due to rounding.

(D) Deleted to avoid disclosure of data pertaining to an individual establishment.

(S) Too small to project.

(*) Total and per capita income are expressed on a residence basis (income of residents of the area). Earnings are on a where earned basis.

> Partial data to avoid disclosure of confidential information in component counties
